1 Session 1 - Summary and Review

1.1 Relationships

1.1.1 Functional

Mathmatical formula Y = f(x)

1.1.2 Statistical

Not a perfect relationship

$$Y = f'(x) + \epsilon$$

observations = trials = case

quadratic = curvilinear

Linear models means that the *slope* is not raised to any powers

- $\hat{y} = \beta_0 + \beta_1 X^2$ is linear
- $\hat{y} = \beta_0 + \beta_1^2 X$ is **not** linear

1.2 Basic Concepts

- Tendency of Y to vary with X in a systematic fashion
- scatter of points around a curve of a statistical relation
- Prob. Distr of Y for each Level of X
- means of Y's distr. to vary for each value of X
 - each point on the regression line can be represented as $\mu_{Y|X_i}$

NOTE: Sir Francis Galton came up with the term "regression"

Regression function of Y on X: Means of the prob. distr. have a systematic relation to the Level of X

Regression curve: graph of the regression function

1.2.1 Construction of Regression models

- 1. Selection of pred. vars
- 2. Functional form of the regression relation
 - Summary plots
 - Scatter plots
- 3. Scope of Model
 - Scope: What is the Domain? (range of X's)
 - Making predictions outside the Domain is considered extrapolation and is dangerous

1.2.2 Uses of Regression Analysis

- 1. Description
- 2. Control
- 3. Prediction (most abused)

Association does not imply causation!

1.3 Simple Linear Regression (SLR)

$$Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$$

- One Predictor
- Linear in the Parameters
- Linear in the Predictor Variables
- SLR = First-Order Model (term from outside of statistics)

 Y_i : Value of the response for the ith trial β_0 : Parameters (unknown. estimate these) X_i : Value of the predictor of the ith term (known) ϵ_i : random error term of the ith observation

1.3.1 Properties of ϵ_i

- $E(\epsilon_i) = 0$
- $\sigma^2(\epsilon_i) = Var(\epsilon_i) = \sigma^2$
- ϵ_i and ϵ_j are uncorrelated

1.3.2 Properties

- 1. Y_i is the sum of two components. It is **random** because its composed of a random term. constant term: $\beta_0 + \beta_1 X_i$ random term: ϵ_i
- 2. $E(Y_i) = E(\beta_0 + \beta_1 X_i + \epsilon_i) \rightarrow E(\beta_0 + \beta_1 X_i) + E(\epsilon_i) \rightarrow \beta_0 + \beta_1 X_i$
- 3. Y_i falls short of regression function by ϵ_i
- 4. $Var(\epsilon_i) = \sigma^2$ error terms have constant variance
- 5. Since error terms are uncorrelated, then responses $(Y_i \text{ and } Y_j \text{ are uncorrelated})$

1.3.3 Alternative forms of SLR

- 1. $Y_i = \beta_0 X_0 + \beta_1 X_i + \epsilon_i$, where $X_0 = 1$
- 2. $Y_i = \beta_0 + \beta_1(X_i \bar{x}) + \beta_1\bar{x} + \epsilon_i \to (\beta_0 + \beta_1\bar{x}) + \beta_1(x_i \bar{x})\epsilon_i)\$ \to \beta_0^* + \beta_1(x_i \bar{x}) + \epsilon_i$

1.3.4 Method of Least Squares

1. Goal Find estimators of β_0 and β_1

For each
$$(X_i, Y_i)$$
: $Y_i - (\beta_0 + \beta_1 X_i) Q = \sum_{i=1}^n [Y_i - \beta_0 - \beta_1 X_i]^2$

b0 and b1 are estimators of β_0 & β_1 that minimize Q for given data $(X_i \ Y_i), \ i=[1, \, n]$

1.3.5 Gauss-Markov Theorem

1. Proof First, lets find the value of b_0 by taking the partial derivative of Q with respect to β_1

$$Q = \sum_{1}^{n} [Y_{i} - \beta_{0} - \beta_{1} X_{i}]^{2}$$

$$\frac{dQ}{d\beta_{1}} = -2 \sum_{1}^{n} X_{i} [Y_{i} - \beta_{0} - \beta_{1} X_{i}]$$

$$\rightarrow \sum_{1}^{n} X_{i} (Y_{i} - b_{0} - b_{1} X_{i}) = 0$$

$$\rightarrow \sum_{1}^{n} X_{i} Y_{i} - b_{0} \sum_{1}^{n} x_{i} - b_{1} \sum_{1}^{n} x_{i}^{2} = 0$$

$$\rightarrow \sum_{1}^{n} Y - i - nb_{0} - b_{1} \sum_{1}^{n} x_{i} = 0$$

$$\rightarrow \sum_{1}^{n} Y_{i} - b_{1} \sum_{1}^{n} x_{i} = nb_{0}$$

$$\rightarrow \bar{Y} - b_{1} \bar{x} = b_{0}$$

$$(1)$$

Once b_0 is found, lets use it to find the value of b_1 . Replace values of b_0 with the equation above.

2. Properties

- (a) $E(b0) = \beta_0 \& E(b1) = \beta_1$
- (b) b0 & b1 are more precise than any other unbiased estimators of β_0 and β_1 that are linear functions of Y_i

1.3.6 Residual

Difference between the observation and the estimated value $i = Y_i - \hat{Y}_i$, i == [1, n]

- 1. $\sum_{i=1}^{n} e_i = 0$
- 2. $\sum_{i=1}^{n} e_i^2$ is a minimum
- 3. $\sum_{i=1}^{n} Y_i = \sum_{i=1}^{n} \hat{Y}_i$
- 1. Goal Estimate σ^2 know $E(S^2) = E(\frac{\sum (Y_i \bar{Y})^2}{n-1})$
 - numerator == sum of squares
 - n 1 == df
 - $S^2 = \text{Mean Square} = \frac{SS}{df}$
- 2. SSE SSE = $\sum (Y_i \hat{Y}_i)^2 = \sum e_i^2$
 - SSE = Sum of Square Error = Residual Sums of Squares
 - MSE = SSE / n 2
 - df of SSE = n 2
 - $E(MSE) = \sigma^2$

1.4 Normal Error Regression Model

 $Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$ where $\epsilon \approx iidN(0, \sigma^2)$, i = [1, n] so $Y_i \approx N(\beta_0 + \beta_1 X_i, \sigma^2)$ To find MLE's of β_0 & β_1 i.e. $\hat{\beta_0}$ & $\hat{\beta_1}$ $L(\beta_0, \beta_1 m \sigma^2) = \prod pdf$

- MLE of β_0 : $\hat{\beta_0} = b_0$
- MLE of β_1 : $\hat{\beta_1} = b_1$

2 Session 2 - Inferences in Regression and Correlation Analysis (2019/09/18)

$$Model = Y_i = \beta_0 \beta_1 X_i + \epsilon_i$$

2.1 Properties

- $\epsilon_i \approx iidN(0, \sigma^2)$
- $Y_i \approx iidN(\beta_0 + \beta_1 X_i, \sigma^2)$
- X_i : known constant
- β_0 & β_1 are parameters to investigate

2.2 β_1

2.2.1Inferences

 $H_0: \beta_1 = 0$ (implies no linear association) $H_1: \beta_1 \neq 0$ This hypothesis test determines if there is a relationship

2.2.2 Sampling Distribution

$$b_1 = \frac{\Sigma((x_i - \bar{x})(y_i - \bar{y}))}{\Sigma(x_i - \bar{x})^2}$$

- $E(b_1) = \beta_1$
- $Var(b_1) = \frac{\sigma^2}{\sum (x_i \bar{x})^2}$

2.2.3 PROOF: b_1 is a linear combination of Y's

- $b_1 = \frac{\Sigma((x_i \bar{x})(y_i \bar{y}))}{\Sigma(x_i \bar{x})^2}$
- $b_1 = \frac{\sum((x_i \bar{x})y_i \bar{y}\sum(x_i \bar{x})}{\sum(x_i \bar{x})^2}$
- $b_1 = \frac{\sum ((x_i \bar{x})y_i)}{\sum (x_i \bar{x})^2}$

Let
$$K_i = \frac{x_i - \bar{x}}{\sum (x_i - \bar{x})^2}$$

Facts about K_i

•
$$\Sigma K_i = \Sigma \frac{x_i - \bar{x}}{\Sigma (X_i - \bar{x})^2} = 0$$

•
$$\Sigma K_i^2 = \Sigma \left(\frac{x_i - \bar{x}}{\Sigma (X_i - \bar{x})^2)^2} = \frac{1}{\Sigma (x_i - \bar{x})^2} \right)$$

•
$$b_1 = \Sigma K - iY_i$$

Therefore b_1 is a linear combination of Y_i

2.2.4 Properties

•
$$E(\hat{\beta}_1) = E(\Sigma K_i Y_i) = \Sigma K_i E(Y_i) = \Sigma K_i (\beta_0 + \beta_1 X_i) = \beta_1 \Sigma K_i X_i = \beta_1$$

More detailed proof of $\Sigma K_i X_i = 1$ exists in notes. It was a sidebar in class.

•
$$\beta_1 \approx N(\beta_1, \frac{\sigma^2}{\Sigma(x_i - \bar{x})^2})$$

•
$$\frac{b_1 - \beta_1}{\sqrt{\frac{\sigma^2}{\sum (x_i - \bar{x})^2}}} \approx N(0, 1)$$

Recall E(MSE) =
$$E(\frac{SSE}{n-2}) = \sigma^2$$

Recall E(MSE) = $E(\frac{SSE}{n-2}) = \sigma^2$ Thus $\frac{b_1-\beta_1}{\sqrt{\frac{MSE}{\Sigma(x_i-\bar{x})^2}}} \approx t_{n-2}$ NOTE: a T Distribution is a standard normal distribution divided by a chi-square distribution scaled by its DF

1. Solving the Hypothesis Test

Recall

$$H_0: \beta_1 = 0 \ H_1: \beta_1 \neq 0$$

Test Statistic

$$t* = \frac{b_1}{\sqrt{\frac{MSE}{\sum (x_i - \bar{x})^2}}} = \frac{b_1}{SE_{b1}} \approx t_{n-2}$$

Then p-value can be calculated

2.3 β_0

$$b_0 \approx N(\beta_0, \sigma^2 \left[\frac{1}{n} + \frac{\bar{x}^2}{\sum (x_i - \bar{x})^2}\right])$$

If Y_i are not exactly normal, b_0 and b_1 are approx. normal. Thus the t statistic provides some level of confidence.

Spacing of X Levels

- The greater the spread of x, the larger $\Sigma (x_i \bar{x})^2$
- $Var(b_1)$ and $Var(b_0)$ decrease

Prediction of new observations

Let a new observation be defined as Y_0

Interval Estimation of $E(Y_0)$

- X_0 : level of x we want to estimate the mean response
- $E(Y_0)$: mean response when $X = X_0$
- $\hat{Y}_0 = b_0 + b_1 X_0$: Point estimate of $E(Y_0)$

2.5.2 Sampling Distribution

$$\begin{split} \hat{Y_0} &\approx N(E(Y_0), \sigma^2[\frac{1}{n} + \frac{(x_0 - \bar{x})^2}{\Sigma(x_i - \bar{x})^2}]) \\ &\hat{Y_0} \pm t_{\frac{\alpha}{2}, n - 2} \sqrt{MSE(\frac{1}{n} + \frac{(X_0 - \bar{x})^2}{\Sigma(x_i - \bar{x})^2})} \\ &\text{NOTE: confidence interval} == \text{mean prediction interval} == \text{sin-production} \end{split}$$

gle value

2.5.3Prediction

 \hat{Y}_1 : predicted individual outcome drawn from the distr. of Y Assumptions

- $E(Y_1)$: estimated by $\hat{Y_1}$
- $Var(Y_1)$: estimated by MSE

$$Var(pred) = Var(\hat{Y}_1) + Var(\hat{Y}_0) = \sigma^2 \left[1 + \frac{1}{n} + \frac{(x_0 - \bar{x})^2}{\Sigma(x_i - \bar{x})^2}\right]$$

100(1 - α)% Prediction Interval

•
$$\hat{Y}_1 \pm t_{\frac{\alpha}{2},n-2} \sqrt{MSE(1+\frac{1}{n}+\frac{(x_0-\bar{x})^2}{\Sigma(x_i-\bar{x})^2})}$$

ANOVA Approach to Regression

Partition the Total Sums of Squares

- 1. When ignoring the predictor variable, Variation is based on $Y_i \bar{Y}$ deviations.
 - SSTo: Total Sums of Squares (or TSS) Therefore, $SSTo = \Sigma (Y_i \bar{y})^2$
- 2. When using the predictor variable, variation based on $Y_i \hat{Y}_i$ deviations. i.e. residuals
 - SSE: Error Sum of Squares Therefore, $SSE = \Sigma (Y_i \hat{Y_i})^2$

SSR: Regression Sum of Squares $SSR = \Sigma (Y_i - \bar{y})^2$ **NOTE**: SSR = SSTo - SSE **OR** SSTo = SSR + SSE. proof is in notebook.

record here if needed

Degrees of Freedom (df)

• SSto: n - 1. $Y_i - \bar{y}$

• SSE: n - 2. $Y_i - \hat{Y}_i$

• SSR: 2 - 1 = 1. $\hat{Y}_i - \bar{y}$

NOTE:

• $E(MSE) = \sigma^2$

• $E(MSR) = \sigma^2 + \beta_1^2 \Sigma (x_i - \bar{x})^2$

Source	SS	$\mathrm{d}\mathrm{f}$	MS	F Statistic
Regression	SSR	1	$MSR = \frac{SSR}{1}$	$F = \frac{MSR}{MSE}$
Error	SSE	n - 2	$MSE = \frac{S\hat{S}E}{n-2}$	111.012
Total	SSTo	n - 1		

F* is the test statistic for

 $H_0: \beta_1 = 0 \ H_1: \beta_1 \neq 0$

 $F^* \approx F_{1,n-2}$ if H_0 is true $(t^*)^2 = F^*$ if $F^* \approx F_{1,n-2}$

3 Session 3 - General Linear Testing & Model Selection (2019/09/25)

3.1 General Linear Test Approach

Full Model: $Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$ where $\epsilon_i \approx iidN(0, \sigma^2)$

This can be fit by either <u>Least Squares</u> or <u>Maximum Likelihood</u>

Notes F = Full Model R = Reduced Model

$$SSE(F) = \Sigma [Y_i - (b_0 + b_1 X_i)]^2$$

$$= \Sigma (Y_i - \hat{Y}_i)^2$$

$$= SSE$$
(3)

3.1.1 Reduced Model

$$H_0: \beta_1 = 0 \text{ if } H_0 \text{ then } Y_i = \beta_0 + \epsilon_i$$

 $H_A: \beta_1 \neq 0$ (4)

Test Statistic: $SSE(F) \leq SSE(R)$

The more parameters in the model, the better the fit **thus** smaller deviations around the fitted regression model.

A small diff suggests H_0 holds. (SSE(R) - SSE(F))

$$F^* = \frac{\frac{SSE(R) - SSE(F)}{df_R - df_F}}{\frac{SSE(F)}{df_F}} \tag{5}$$

Note: The full model has less variation because the hope is that the predictor (X) helps explain the spread in the response (Y).

p-value = $P(F_{df_R-df_F,df_F} \ge F^*)$ For SLR and testing the null hypothesis $(H_0: \beta_1 = 0)$,

$$F^* = \frac{\frac{SSTo - SSE}{(n-1) - (n-2)}}{\frac{SSE}{n-2}}$$

$$= \frac{SSR}{MSE}$$

$$= \frac{MSR}{MSE}$$
(6)

This is exactly like the ANOVA table!

3.1.2 Coefficients of Determination (R^2)

Goal: Quantify how much variation in the repsonse is explained by the model. **Def**: The proportion of variation in Y explained by regressing Y on X.

$$R^2 = \frac{SSR}{SSTo} = 1 - \frac{SSE}{SSTo}$$

Properties

- $0 \le R^2 \le 1$
- $R^2 = 1$ indicates a perfect fit
- $R^2 = 0 \rightarrow b_1 = 0$ thus a horizontal line \mathbf{OR} a non-linear pattern

A high \mathbb{R}^2 value does NOT indicate

- useful predictions can be made
- estimated regression line is a good fit
- x and y are related

3.1.3 Coefficient of Correlation: $r = \pm \sqrt{R^2}$

A measure of the linear association between Y and X when Y and X are random variables. **Properties**

- $\bullet \ -1 \le r \le 1$
- sign of correlation matches sign of slope

3.2 Assessing the Quality of a Model

Diagnostics for X (predictor variable)

- 1. Dot Plot
- 2. Sequence Plot $X_1, ..., X_n$. No pattern is good
- 3. Stem-and-Leaf plot (< 100 observations)
- 4. Box Plot
- 5. Histogram

3.2.1 Residuals (observed error)

$$e_i = Y_i \hat{Y}_i$$

Properties

- $\bar{e} = \frac{\sum e_i}{n} = 0$
- $S_e^2 = \frac{\Sigma (e_i \bar{e})^2}{n-2} = \frac{\Sigma e_i^2}{n-2} = \frac{SSE}{n-2} = MSE$
- e_i 's are **not** independent random variables.
 - If large n, the dependence of e_i is relatively unimportant and can be ignored

Standardized vs Studentized

- Standardized = $\frac{Y_i \bar{y}}{\sigma}$
- Studentized = $\frac{Y_i \mu}{\frac{\sigma}{n}}$

Semi-studentized Residuals $e_i^* = \frac{e_i - \bar{e}}{\sqrt{MSE}} = \frac{e_i}{\sqrt{MSE}}$

3.2.2 Residual Plots

Residual Plot Form

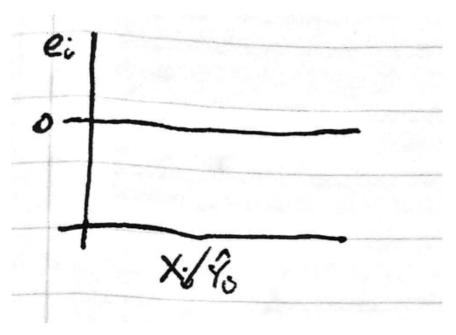

Figure 1: Empty Residual Plot

1. Tests

- (a) Non-linearity of regression function A pattern indicates linear regression not appropriate
- (a) Non-constancy of error terms Fanning indicates different variances for different values of $X_i or \hat{Y}_i$
- (b) Presence of outliers Graph Semi-studentized residuals on a Residual plot \mathbf{OR} a Box Plot if $|e_i^*| \geq 4$, outlier

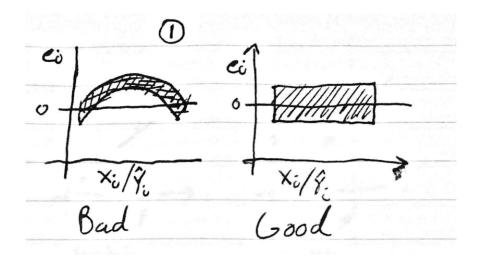

Figure 2: Plots 1

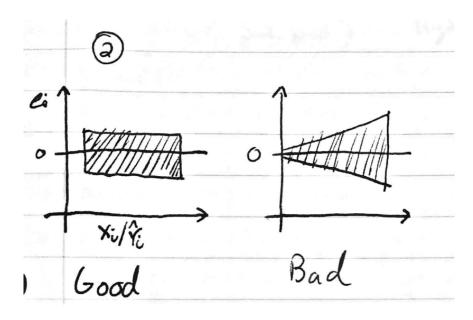

Figure 3: Plots 2

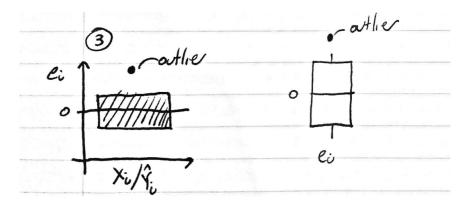

Figure 4: Plots 3

(c) Non-independence of error terms (more of a concern with timeseries) No pattern is good. Error terms safe to assume independent.

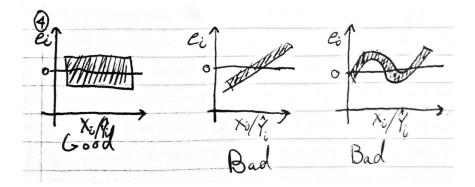

Figure 5: Plots 4

- (d) Normality of Error Terms
 - Use a normal probability plot. The closer the points the fall on a straight line, the closer they are to a normal distribution.
- (e) Omission of Important Predictors? A Pattern indicates that there might be a relationshup between the residuals and some other predictor. This can be used to determine whether a predictor should be used before modeling it. Probably not as necessary anymore since it is easy to run and compare models.

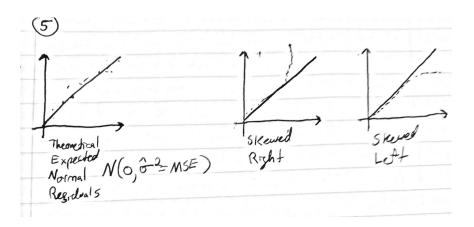

Figure 6: Plots 5

3.2.3 Test of Randomness

1. Durbin-Watson Test

$$H_0: \phi = 0$$
 where ϕ is an autocorrelation coefficient $H_A: \phi > 0$ most assume positive correlation (7)

lmtest::dwtest(modle)

2. Shapiro-Wilk Test for Normality Not writing much here because I know it already

shapiro.test()

3.2.4 Constant Variance

1. Brown-Forsyth Test Robust since it uses Median

lawstat::levene.test()

2. Breusch-Pagan Test Sensitive to departures from Normality $log(\sigma^2) = \gamma_0 + \gamma_1 x_i$

$$H_0: \gamma_1 = 0$$

$$H_A: \gamma_1 \neq 0$$
(8)

lmtest::bptest()

NOTES: Heteroscedascity means non-constant variance

4 Session 4 - Transformations & Inference (2019/10/02)

4.1 Transformations

If non-normality and unequal error variance:

1. Transform Y: Y' = f(Y)

2. Transform X: X' = f(X)

If non-linearity (rarer)

1. Transform X: X' = f(X)

In order to determine which transformation to choose, look at the raw data and make a judgement call.

In Class Example

$$\overline{Y_i' = log(Y_i) = \beta_0} + \beta_1 X_i + \epsilon_i \equiv Y_i = exp(\beta_0 + \beta_1 X_i + \epsilon_i)i$$

A 1 unit increase in X is associated with a $exp(\beta_1)$ multiplicative effect on the **geometric** mean. This link explains in detail the impact of log transformed variables.

Geometric mean = $(\Pi x_i)^{\frac{1}{n}}$

$$\hat{Y}_i = log(Y)$$

$$X_i' = \sqrt{x}$$

$$\hat{Y}_i = 4.896 + 4.325X_i' \rightarrow exp(4.235) = 75.528$$

For each 1 unit increase in X', the estimated increase in the geometric mean price is 75.53 times its previous value.

4.1.1 Box-Cox Transformations

There is a value λ that is the optimal transformation to the response for equal variance and normality. It is optimal in the sense that it finds the value of λ which produces the smallest SSE for Y_i .

$$Y_i^{\lambda} = \beta_0 + \beta_1 X_i + \epsilon_i \text{where } i \sim \text{iid } N(0, \sigma^2)$$

lindia::gg-boxcox(model)

4.2 Simultaneous Inference

Goal: Try to estimate more than one mean response at a time. $(0.95)^3 = 0.857375$

4.2.1 Working-Hotelling Procedure

Based on the confidence band for the regression line.

100(1 -
$$\alpha$$
)% simultanous confidence limits for g mean responses $E(Y_h)$ $Y_h \pm W \sqrt{MSE(\frac{1}{n} + \frac{(X_h - \bar{X})^2}{\Sigma(X_i - \bar{X})^2})}$ where $W^2 = 2F_{1-\alpha,2,n-2}$

 $qf(1 - \alpha, n - 2)$

4.2.2 Bonferonni Procedure

$$Y_h \pm B\sqrt{MSE(\frac{1}{n} + \frac{(X_h - \bar{X})^2}{\Sigma(X_i - \bar{X})^2})}$$
 where $B = t_{1-\frac{\alpha}{2g},n-2}$

qt(1 - alpha / 2g, n - 2)

5 Session 5 - Prediction & Linear Algebra in Regression

5.1 Simultaneous Intervals

5.1.1 Confidence

Using the Bonferonni adjustment, The simultaneous confidence interval for mean winning percentage for RunDiff of $X_h=-100,0,100$ has a confidence level $=1-\frac{\alpha}{q}$ where $\alpha=.05$ and g=3

This is good for a smaller number of predictors. i.e. g < 10

5.1.2 Prediction

Bonferroni:
$$\hat{Y}_h \pm t_{1-\frac{\alpha}{2g},n-2} \sqrt{\text{MSE}(1+\frac{1}{n}+\frac{(x_h-\bar{x})^2}{\Sigma(x_i-\bar{x})^2})}$$
 level = $1-\frac{\alpha}{g}$
Scheffe: $\hat{Y}_h \pm S \sqrt{\text{MSE}(1+\frac{1}{n}+\frac{(x_h-\bar{x})^2}{\Sigma(x_i-\bar{x})^2})}$ where $S = \sqrt{gF_{1-\alpha,g,n-2}}$

Scheffe is more efficient with a larger \mathbf{g} (i.e. g > 10). An in-class example showed that this was not the case so the jury is still out.

Inverse Prediction ("Calibration")

First, construct a model where Y = X

Goal: Make a prediction of X that was used to predict a new value of Y.

$$\hat{Y}_i = \beta_0 + \beta_1 X_i + \epsilon_i \text{ where } \epsilon_i \sim \text{ iid } N(0, \sigma^2)$$

$$\hat{Y} = b_0 + b_1 x$$
(9)

We are given $Y_{h(new)}$, so what is $X_{h(new)}$? $X_h(\hat{n}ew) = \frac{Y_{h(new)} - b_0}{b_1}$

$$X_h(\hat{n}ew) = \frac{Y_{h(new)} - b_0}{b_0}$$

$$X_{h(new)} \pm t_{1-\frac{\alpha}{2},n-2} \sqrt{\frac{MSE}{b_1^2} (1 + \frac{1}{n} + \frac{(x_{h(new)} - \bar{x})^2}{\sum (x_i - \bar{x})^2})}$$

investr::calibrate(model, Y, interval = "Wald")

The approximate confidence interval is appropriate if the following quantity is small (i.e. < .1):

$$\frac{t_{1-\frac{\alpha}{2},n-2}^2 \mathring{MSE}}{b_1^2 \Sigma (X_i - \bar{X})^2}$$

Linear Algebra in Regression 5.3

5.3.1 Review

$$ec{Y}_{(nX1)} = egin{bmatrix} Y_1 \\ Y_2 \\ \dots \\ Y_n \end{bmatrix}$$
 $ec{Y^T}_{(1 imes n)} = egin{bmatrix} Y_1 & \dots & Y_n \end{bmatrix}$
Design Matrix

Design Wattra
$$X = \begin{bmatrix} 1 & x_1 \\ 1 & x_2 \\ \dots & \dots \\ 1 & x_n \end{bmatrix}$$

$$x^T = \begin{bmatrix} 1 & \dots & 1 \\ x_1 & \dots & x_n \end{bmatrix}$$

1. Matrix Addition & Subtraction

$$Y_{i} = E(Y_{i}) + \epsilon_{i}$$

$$\vec{Y} = E(\vec{Y}) + \vec{\epsilon}$$

$$E(\vec{Y}) = \begin{bmatrix} E(Y_{1}) \\ \dots \\ E(Y_{n}) \end{bmatrix}$$

$$\vec{\epsilon} = \begin{bmatrix} \epsilon_{1} \\ \dots \\ \epsilon_{n} \end{bmatrix}$$
(10)

2. Matrix Multiplication

$$\vec{Y}^T \vec{Y}_{(1 \times n)(n \times 1)} = \begin{bmatrix} Y_1 & \dots & Y_n \end{bmatrix} \begin{bmatrix} Y_1 \\ \dots \\ Y_n \end{bmatrix} = \sum_{1}^{n} Y_i^2$$

$$\vec{X}^T \vec{X}_{(2 \times n)(n \times 2)} = \begin{bmatrix} 1 & \dots & 1 \\ x_1 & \dots & x_n \end{bmatrix} \begin{bmatrix} 1 & x_1 \\ \dots & \dots \\ 1 & x_n \end{bmatrix} = \begin{bmatrix} n & \Sigma X_i \\ \Sigma X_i & \Sigma X_i^2 \end{bmatrix} \qquad (11)$$

$$\vec{X}^T \vec{Y}_{(2 \times n)(n \times 1)} = \begin{bmatrix} 1 & \dots & 1 \\ x_1 & \dots & x_n \end{bmatrix} \begin{bmatrix} Y_1 \\ \dots \\ Y_n \end{bmatrix} = \begin{bmatrix} \Sigma Y_i \\ \Sigma X_i Y_i \end{bmatrix}$$

3. Special Matrices **Symmetric**: $A = A^T$ This implies a square matrix. i.e. n x n

Diagonal:
$$A = \begin{bmatrix} a_{11} & 0 & \dots & 0 \\ 0 & a_{22} & \dots & 0 \\ \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & a_{nn} \end{bmatrix}$$

$$\textbf{Identity Matrix: } \underbrace{I}_{(n \times n)} = \begin{bmatrix} 1 & \dots & 0 \\ \dots & 1 & \dots \\ 0 & \dots & 1 \end{bmatrix}$$

Scalar:
$$gI = \begin{bmatrix} g & \dots & 0 \\ \dots & g & \dots \\ 0 & \dots & g \end{bmatrix}$$
 where g is a scalar value

One vectors

$$\vec{1}_{(n\times1)} = \begin{bmatrix} 1 \\ \dots \\ 1 \end{bmatrix}
J_{(n\times n)} = \begin{bmatrix} 1 & \dots & 1 \\ \dots & 1 & \dots \\ 1 & \dots & 1 \end{bmatrix}
\vec{1}^T \vec{1}_{(1\times n)(n\times1)} = n
\vec{1}^T \vec{1}_{(n\times1)(1\times n)} = \begin{bmatrix} 1 \\ \dots \\ 1 \end{bmatrix} \begin{bmatrix} 1 & \dots & 1 \end{bmatrix} = J$$
(12)

4. Inverse of a Matrix

$$A_{(2\times2)} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}
A_{(2\times2)} = \frac{1}{\det(A)} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix} = \frac{1}{ad - bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$$
(13)

Application to Regression

$$(X^{T}X)^{-1} = \frac{1}{\det(X^{T}X)} \begin{bmatrix} \Sigma x_{i}^{2} & -\Sigma x_{i} \\ -\Sigma x_{i} & n \end{bmatrix} = \dots = \begin{bmatrix} \frac{\Sigma x_{i}^{2}}{n\Sigma(x_{i}-\bar{x})^{2}} & -\frac{\Sigma x_{i}}{n\Sigma(x_{i}-\bar{x})^{2}} \\ -\frac{\Sigma x_{i}}{n\Sigma(x_{i}-\bar{x})^{2}} & \frac{n}{n\Sigma(x_{i}-\bar{x})^{2}} \end{bmatrix}$$

$$\det(X^{T}X) = n\Sigma x_{i}^{2} - (\Sigma x_{i})^{2}$$

$$= n\Sigma x_{i}^{2} - \frac{n(\Sigma x_{i})^{2}}{n^{2}}$$

$$= n[\Sigma x_{i}^{2} - \frac{(\Sigma x_{i})^{2}}{n}]$$

$$= n\Sigma(x_{i} - \bar{x})^{2}$$

$$(14)$$

Side Note

$$\Sigma x_{i} = n\bar{x}$$

$$\Sigma (x_{i} - \bar{x})^{2} = \Sigma x_{i}^{2} - n\bar{x}^{2}$$

$$\Sigma x_{i}^{2} = \Sigma (x_{i} - \bar{x})^{2} + n\bar{x}^{2}$$

$$(X^{T}X)^{-1} = \begin{bmatrix} \frac{1}{n} + \frac{\bar{x}^{2}}{\Sigma(x_{i} - \bar{x})^{2}} & -\frac{\bar{x}}{\Sigma(x_{i} - \bar{x})^{2}} \\ -\frac{\bar{x}}{\Sigma(x_{i} - \bar{x})^{2}} & \frac{1}{\Sigma(x_{i} - \bar{x})^{2}} \end{bmatrix}$$
(15)

5. Matrix Rules

$$A + B = B + A$$
$$(A + B) + C = A + (B + C)$$
$$(AB)C = A(BC)$$
$$C(A + B) = CA + CB$$

$$(A^{T})^{T} = A$$

$$(A+B)^{T} = A^{T} + B^{T}$$

$$(AB)^{T} = B^{T} A^{T}$$
(16)

$$(AB)^{-1} = B^{-1}A^{-1}$$

 $(A^{-1})^{-1} = A$
 $(A^{T})^{-1} = (A^{-1})^{T}$

5.3.2 Expectations

$$\vec{Y}_{(n\times1)} = \begin{bmatrix} Y_1 \\ \dots \\ Y_n \end{bmatrix} \\
E(\vec{Y}) = \begin{bmatrix} E(Y_1) \\ \dots \\ E(Y_n) \end{bmatrix} \\
\vec{\epsilon} = \begin{bmatrix} \epsilon_1 \\ \dots \\ \epsilon_n \end{bmatrix} \\
E(\vec{\epsilon}) = \vec{0}$$
(17)

5.3.3 Variance-Covariance Matrix

$$\sigma^{2}(\vec{Y}) = \begin{bmatrix} Var(Y_{i}) & \dots & Cov(Y_{1}, Y_{n}) \\ \dots & \dots & \dots \\ Cov(Y_{n}, Y_{1}) & \dots & Var(Y_{n}) \end{bmatrix}$$
(18)

When Y_i independent, the off diagonals are 0 meaning $\sigma^2(\vec{Y}) = \sigma^2 I$ Aside

$$Var(Y) = E[(Y - E(Y))^{2}]$$

$$\sigma^{2}(\vec{Y}) = E[(\vec{Y} - E(\vec{Y}))(\vec{Y} - E(\vec{Y}))^{T}]$$
(19)

Let $\vec{W}_{(p\times 1)}=A\vec{Y}_{(p\times n)(n\times 1)}$ where A is a matrix of **constants** and Y is a random vector

$$E(A) = A$$

$$E(\vec{W}) = AE(\vec{Y})$$

$$\sigma^{2}(\vec{W}) = E[(\vec{W} - E(\vec{W}))(\vec{W} - E(\vec{W}))^{T}]$$

$$= E[(A\vec{Y} - AE(\vec{Y}))(A\vec{Y} - AE(\vec{Y}))^{T}]$$

$$= E[A(\vec{Y} - E(\vec{Y}))(A(\vec{Y} - E(\vec{Y}))^{T}]$$

$$= E[A(\vec{Y} - E(\vec{Y}))(\vec{Y} - E(\vec{Y}))^{T}A^{T}]$$

$$= AE[(\vec{Y} - E(\vec{Y}))(\vec{Y} - E(\vec{Y}))^{T}]A^{T}$$

$$= A\sigma^{2}(\vec{Y})A^{T}$$
(20)

5.3.4 Multivariate Normal Distribution

$$\vec{Y}_{(p\times1)} = \begin{bmatrix} Y_1 \\ \dots \\ Y_p \end{bmatrix} \\
\vec{\mu}_{(p\times1)} = \begin{bmatrix} \mu_1 \\ \dots \\ \mu_p \end{bmatrix} \tag{21}$$

 $\sum_{(p \times p)}$ = Variance-Covariance Matrix

$$f(\vec{Y}) = \frac{1}{(2\pi)^{\frac{P}{2}} \sqrt{\det(\Sigma)}} exp(-\frac{1}{2}(\vec{Y} - \vec{\mu})^T \Sigma^{-1}(\vec{Y} - \vec{\mu}))$$

If $Y_1, ..., Y_p$ are jointly normally distributed (i.e in the multivariate normal distr.), then $Y_k \sim N(\mu_k, \sigma_k^2)$ where k = [1, p]

Recall the Linear Regression equation $Y_i\beta_0 + \beta_1X_i + \epsilon_i$ where $\epsilon_i \sim$ $N(0,\sigma^2)$.

$$\vec{Y} = X\vec{\beta} + \vec{\epsilon} \text{ where } \vec{\epsilon} \sim N_n(\vec{0}, \sigma^2 I)$$

 N_n is a dimensions of a multivariate normal

$$\vec{\beta} = \begin{bmatrix} \beta_0 \\ \beta_1 \end{bmatrix}$$
$$E(\vec{Y}) = X\vec{\beta}$$

5.3.5 Least Squares Estimation

Normal Equations from Week 2

$$nb_o + b_1 \Sigma x_i = \Sigma Y_i$$

$$b_0 \Sigma X_i + b_1 \Sigma X_i^2 = \Sigma X_i Y_i$$
(22)

$$X^T X \vec{b} = X^T \vec{Y}$$

Least Squares Estimator:
$$\vec{b} = (X^T X)^{-1} X^T \vec{Y}$$

$$\hat{\hat{Y}}_{(n \times 1)} = X \vec{b}_{(n \times 2)(2 \times 1)} = (X^T X)^{-1} X^T \vec{Y}$$

1. Hat Matrix $H = (X^T X)^{-1} X^T$

The Hat Matrix is important for computing diagnostics for the model such as Cook's Distance.

Properties

- symmetric $(H^T = H)$
- Idempotent (HH = H)

2. Residuals
$$E_i = Y_i - \hat{Y}_i \rightarrow \vec{Y} - \vec{\hat{Y}} = \vec{Y} - X\vec{b} = \vec{Y} - H\vec{Y} = (I - H)\vec{Y}$$

$$\sigma^2(\vec{e}) = \sigma^2(I - H)$$

This is estimated by: MSE(I-H)

Session 6 - Sums of Squares and Multiple Linear 6 Regression

Sum of Squares 6.1

$$\vec{Y}^T \vec{Y}_{(1 \times n)(n \ times1)} = \Sigma Y_i^2 \tag{23}$$

Quadratic Form: Contains squares of observations **and** their cross products. These are known as second-degree polynomials.

Quadratic forms scaled by σ^2 allow us to treat the random variable Y as an observation of χ^2_{n-1} distribution.

This is unlike $\sigma^2(\vec{A}\vec{Y}) = A\sigma^2(\vec{Y})A^T$ since that is squaring a matrix of **constants** whereas $\vec{Y}^T\vec{Y}$ squares a matrix of **random variables** i.e. Y

6.1.1 SSE

$$SSE = \sum e_i^2$$

$$= \vec{e}^T \vec{e}$$

$$= \vec{Y}^T (I - H) \vec{Y}$$
(24)

6.1.2 SSTo

$$SSTo = \Sigma (Y_i - \bar{Y})^2$$

$$= \Sigma Y_i^2 - \frac{(\Sigma Y_i)^2}{n}$$

$$= \vec{Y}^T (I - \frac{1}{n}J)\vec{Y}$$
(25)

6.1.3 SSR

$$SSR = \Sigma (\hat{Y}_i - \bar{Y})^2$$

$$= \vec{Y}^T (H - \frac{1}{n}J)\vec{Y}$$
(26)

6.2 Mean Estimates σ^2

6.2.1 Mean Responses

$$\hat{Y}_h = b_0 + b_1 X_h$$
 so? we would like

$$\hat{Y}_h = \begin{bmatrix} 1 & X_h \end{bmatrix} \vec{b}$$
(27)

Let
$$\vec{X_h} = \begin{bmatrix} 1 \\ X_h \end{bmatrix}$$

Then, $\hat{Y_h} = \vec{X_h}^T \vec{b}$

This is an estimate of the mean response!

6.3 Variance of \hat{Y}_h

$$Var(\hat{Y}_{h}) = Var(\vec{X}_{h}^{T}\vec{b})$$

$$= \vec{X}_{h}^{T}Var(\vec{b})\vec{X}_{h}$$

$$= \vec{X}_{h}^{T}\sigma^{2}(X^{T}X)^{-1}\vec{X}_{h}$$

$$= \sigma^{2}X_{h}^{T}(X^{T}X)^{-1}\vec{X}_{h}$$

$$= (1\times2)(2\times2)(2\times1)$$
(28)

6.4 Multiple Regression Models

$$Y_i = \beta_0 + \beta_1 X_{i1} + ... + \beta_{p-1} X_{i,p-1} + \epsilon_i \text{ where } \epsilon_i \sim iidN(0, \sigma^2)$$

 $E(Y_i) = \beta_0 + \beta_1 X_{i1} + ... + \beta_{p-1} X_{i,p-1}$
 $Y_i \sim indepN(E(Y_i), \sigma^2).$

The parameters of this model are $\{\beta_0, \ldots, \beta_p\}$. Thus there are **p** regression coefficients.

6.4.1 Interpretation

Using the model, $Y_i = \beta_0 + \beta_1 X_{i,1} + \beta_2 X_{i,2}$

let's interpret the coefficients.

 β_0 : The mean response of Y when $X_1 = 0, X_2 = 0$

 β_1 : For a fixed value of X_2 , the associated increase in mean response in Y is β_1 for every 1 unit increase in X_1 . This is known as a partial effect

 β_2 : For a fixed value of X_1 , the associated increase in mean response in Y is β_2 for every 1 unit increase in X_2 .

 β_k : Associated change in mean response of Y for every 1 unit increase in X_k , given all other predictors are held constant.

6.4.2 Aside: Multi-Collinearity

Multicollinearity occurs when two or more predictors are highly correlated.

- Standard Errors blow up which makes test statistic small, which makes p-values high. This affects the ability for us to make **inferences**
- Multicollinearity is acceptable when using models for **prediction** but not when using them for **inference**.

Matrix Notation 6.4.3

$$\frac{\vec{Y}}{(n\times1)} = X\vec{\beta} + \vec{\epsilon}
(n\times p)(p\times1) + (n\times1)$$

$$Var(\vec{\epsilon}) = \sigma^2 I
(n\times n)$$
(29)

- 1. Fitted Values $\hat{Y}_i = b_0 + b_1 X_{i,1} + \dots + b_{p-1} X_{i,p-1}$ Residuals: $e_i = Y_i - \hat{Y}_i$
- 2. Least Squares Estimators

$$\vec{b}_{(p\times 1)} = (X^TX)^{-1} X^T\vec{Y}_{(p\times n)(n\times p)(p\times n)(n\times 1)}$$

6.4.4 ANOVA Table

Source	SS	DF	MS	F	p-value
Regression	$SSR = \Sigma (\hat{Y}_i - \bar{Y})^2$	p - 1	$MSR = \frac{SSR}{p-1}$	$F^* = \frac{MSR}{MSE}$	$P(F_{p-1,n-p} \ge F^*)$
Error	$\mathrm{SSE} = \Sigma (Y_i - \hat{Y}_i)^2$	n - p	$MSE = \frac{SSE}{n-p}$		
Total	$\mathrm{SSto} = \Sigma (Y_i - \bar{Y})^2$	n - 1	1		

Omnibus F-Test for Regression Relation

$$H_0: \beta_1 = \beta_2 = \dots = \beta_p = 0$$

$$H_A: \text{ at least one } \beta_k \neq 0$$
(30)

Test statistic: $F^* = \frac{MSR}{MSE}$. If H_0 is true, $F^* \sim F_{p-1,n-p}$

6.4.6 Coefficient of Multiple Determination

$$R^2 = 1 - \frac{SSE}{SSTo}$$

 $R^2=1-\frac{SSE}{SSTo}$ The issue with R^2 is that it increases with the number of predictors irrespective of the predictor improving the model.

$$R_{adj}^2 = 1 - \frac{\frac{SSE}{n-p}}{\frac{SSTo}{n-1}}$$

6.4.7 Coefficient of Multiple Correlation

$$R=\sqrt{R^2}$$

6.4.8 Inferences in β_k

$$H_0: \beta_k = 0$$

$$H_A: \beta_k \neq 0$$
(31)

Test Statistic:
$$t^* = \frac{b_k}{SE_{bk}}$$

If H_0 is true, then $t^* \sim t_{n-p}$
p-value = $2P(t_{n-p} \ge |t|)$

2 * (1 - pt(abs(t.star), n - p))
$$100(1-\alpha)SE_{bk}$$

7 Session 7 - Multiple Regression & Qualitative \setminus Quantitative Predictors

7.1 Multiple Regression

7.1.1 Extra Sums of Squares

Def: The marginal reduction in SSE when one or several predictors are added to the regression model, **given** other predictors are already in the model.

$$SSR(X_2|X_1) = SSE(X_1) - SSE(X_1, X_2)$$

 $SSR(X_2|X_1) = SSR(X_1, X_2) - SSR(X_1)$

These are equivalent because any reduction in SSE implies an increase in SSR per the ANOVA definition: SSTo = SSR + SSE

1. Multiple Predictors

$$SSR(X_3|X_1, X_2) = SSE(X_1, X_2) - SSE(X_1, X_2, X_3)$$

 $SSR(X_3|X_1, X_2) = SSR(X_1, X_2, X_3) - SSR(X_1, X_2)$
 $SSR(X_1, X_2) = SSR(X_2) + SSR(X_1|X_2)$

Source	SS	$\mathrm{d}\mathrm{f}$	MSE
Regression	$SSR(X_1, X_2, X_3)$	3	$\overline{MSR(X_1,X_2,X_3)}$
X_1	$SSR(X_1)$	1	$MSR(X_1)$
$X_2 X_1$	$SSR(X_2 X_1)$	1	$MSR(X_2 X_3)$
$X_3 X_1, X_2$	$SSR(X_3 X_1,X_2)$	1	$MSR(X_3 X_1,X_2)$ \$
Error	$SSE(X_1, X_2, X_3)$	n - 4	$MSE(X_1, X_2, X_3)$
Total	SSTo	n - 1	

2. Hypothesis Test - $\beta_k = 0$ $H_0: \mu_k = 0$

$$H_A: \mu_k \neq 0$$

This is the $\mu_k X_k$ dropped from the model.

Test Statistic: $t^* = \frac{b_k}{SE_{bk}} df = n - p$

- (a) Full model $Y_i = \mu_0 + \mu_1 X_1 + ... + \mu_{p-1} X_{i,p-1} + \epsilon_i$ "p - 1" predictor variables $SSE(F) = SSE(X, ..., X_{p-1})$
- (b) Reduced Model $Y_i = \mu_0 + \mu_1 X_1 + ... + \mu_{p-2} X_{i,p-2} + \epsilon_i$ "p - 2" predictor variables $SSE(R) = SSR(X, ..., X_{k-1}, X_{p-1})$ $F^* = SSE(R) - SSE(F) = \frac{df_R - df_F}{\frac{SSE(F)}{df_F}} = \frac{\frac{SSE(X_1, ..., X_{k-1}, X_k, ..., X_{p-1}) - SSE(X, ..., X_{p-1})}{\frac{SSE(X, ..., X_{p-1})}{n-p}}$
- 3. Hypothesis Test $\beta_0 = \dots = \beta_k = 0$
 - $\begin{array}{l} \text{(a)} \ \ \text{Reduced Model} \ Y_i = \mu_0 + \mu_1 X_{i1} + \ldots + \mu_{k-1} X_{i,k-1} + \mu_k X_{ik} + \ldots + \\ \mu_{p-1} X_{i,p-1} + \epsilon_i \\ \ \ \text{"p-g-1" predictors} \ \mathbf{OR} \ \ \text{"p-g" regression coefficients} \\ F^* = \frac{\frac{SSE(X_1,\ldots,X_{k-1},X_k,\ldots,X_{p-1}) SSE(X,\ldots,X_{p-1})}{\frac{n-(p-g)-(n-p)}{n-p}}}{\frac{SSE(X,\ldots,X_{p-1})}{n-p}} = \frac{SSR(X_k,\ldots,X_{k+(g-1)}|X_k,\ldots,X_{k+g},\ldots,X_{p-1})}{MSE(X_1,\ldots,X_{p-1})} \\ \text{If} \ H_0 \ \text{is true}, \ F^* \sim F_{g,n-p} \end{array}$
- 4. R^2 R^2 : Coefficient of multiple determination
 - proportion of variation in Y explained by the regression of Y on $X_1,...,X_{p-1}$

$$\underline{\mathbf{E}}\mathbf{x}$$

$$Y_i = \mu_0 + \mu_1 X_{i,1} + \mu_2 X_{i,2}$$

 $SSE(X_2)$: variation when only X_2 is in the model.

 $SSE(X_1, X_2)$: variation when both X_1, X_2 are in the model.

Marginal reduction in variation when X_1 is added to the model?

$$\frac{SSE(X_2) - SSE(X_1, X_2)}{SSE(X_2)}$$

$$R_{Y_1/Y_2}^2 = \frac{SSR(X_1|X_2)}{SSE(X_2)}$$

$$R_{Y_2/Y_1}^2 = \frac{SSR(X_2|X_1)}{SSE(X_1)}$$

3 predictors

$$R_{Y3|2,1}^2 = \frac{SSR(X_3|X_1,X_2)}{SSE(X_1,X_2)}$$

Recipe for correlation coefficient:

- (a) Take sqrt of partial R^2
- (b) Sign of partial correlation = sign of correlation corresponding coefficient

7.2 Multi-collinearity

Predictors that are highly correlated with each other. 10 N values per predictor

7.2.1 Effects

- 1. There is no unique sum of squares that can be assigned to the predictor variable
- 2. May inflate standard error of b_k least square error.

It does not greatly impact the value of predictions. ETA^2 tells R^2 given the previously given variable R^2

7.3 Polynomial Regression Models

- true curvilinear response
- true curvilinear response is unknown but a polynomial function provides a good approximation to the true function.

One prediction variable and second order:

$$Y_i = \mu_0 + \mu_1 X + \mu_2 X^2 + \epsilon_i$$
 where $X_i = x_i - \bar{x}$

$$E(Y) = \mu_0 + \mu_1 X_1 + \mu_2 X^2$$

Two parameters and second order:

$$x_{i,1} = x_{i,1} - \bar{x_1}$$

$$X_{i,2} = x_{i,2} - \bar{x_2}$$

$$Y_{i} = \beta_{0}\beta_{1}X_{i,1} + \beta_{2}X_{i,2} + \beta_{3}X_{i,1}^{2} + \beta_{4}X_{i,2}^{2} + \beta_{5}X_{i,1}X_{i,2} + \epsilon_{i}$$

Strategy? Fit higher order models and compare to reduced models.

summary(model)

$$\hat{Y} = b_0 + b_1 x + b_2 x^2 \ \hat{Y} = b_0' + b_1' x + b_2' x^2$$

$$b_0' = b_0 - b_1 \bar{x} - b_2 \bar{x}^2$$

$$b_1' = b_1 - 2b_2\bar{x}$$

$$b_2' = b_2$$

Why do this? Solving a regression model with a non-linear $E(Y_i)$

8 Session 8 - Interaction Models & Model Selection

8.1 Interaction Regression Models

- p: # of regression coefficients. i.e. parameters
- p 1: predictor variables

8.1.1 Additive Effects

$$E(Y) = \sum_{i=1}^{p-1} f_K(x_k)$$
 (32)

but $E(Y) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 \beta_3 X_1 X_2$ is **not** additive since $X_1 X_2$ is an interaction term

Consider the following:

$$Y_i = \beta_0 + \beta_1 X_1 + \beta_2 X_2 \ \beta_3 X_1 X_2 + \epsilon_i \text{ where } \epsilon_i \sim iidN(0, \sigma^2)$$

A one-unit **increase** in X_2 for a fixed value of X_1 , results in an associated change of $\beta_1 + \beta_3 X_1$ units in mean response Y.

- $\beta_3 = 0 => additive model$
- $\beta_3 > 0 =$ reinforcement or synergistic interaction*
- $\beta_3 < 0 =>$ interference or antagonistic interaction*

*if β_1 and β_2 are negative, these terms flip parallel lines indicate **additive** terms, otherwise interactive **Aside**

To avoid multicollinearity between predictors, center variables! $X_{ik} = X_{ik} - \bar{X}_k$

Does Standardizing also help reduce multicollinearity? Yes, but makes interpretation more difficult. This is done in PCA and as I've seen, interpreting PCA can be hairy or a best guess.

- Try to identify possible interactions ahead of time prior to fitting the model.
- When looking at removing **one** term, the t statistic is sufficient to rule out a parameter.

8.1.2 Qualitative Predictors

Qualitative Predictor with two classes. i.e. two values This is sometimes called: Indicators, Binary, dummy variables

For representing C classes, use C-1 indicator variables.

Example

Let
$$C = 4$$
 $C = \begin{bmatrix} A \\ B \\ C \\ D \end{bmatrix}$

$$Y_{i} = \beta_{0} + \beta_{1}X_{1} + \beta_{2}X_{2} \ \beta_{3}X_{3} + \beta_{4}X_{4} + \epsilon_{i} \text{ where}$$

$$X_{2} = \begin{cases} 1, & A \\ 0, & else \end{cases}$$

$$X_{3} = \begin{cases} 1, & B \\ 0, & else \end{cases}$$

$$X_{4} = \begin{cases} 1, & C \\ 0, & else \end{cases}$$

$$(33)$$

if $X_2 = X_3 = X_4 = 0$, indicates effect of C = D on mean Y_i

$$A: E(Y) = (\beta_0 + \beta_2) + \beta_1 X_i$$

$$B: E(Y) = (\beta_0 + \beta_3) + \beta_1 X_i$$

$$C: E(Y) = (\beta_0 + \beta_4) + \beta_1 X_i$$

$$D: E(Y) = (\beta_0) + \beta_1 X_i$$
(34)

D is considered the baseline category

1 Qualitative variable and 1 Quantitative variable in the same model is known as **ancova**: Analysis of Covariance. ANCOVA assumes that each group has the same slope.

Interpret β_0 : The diff in mean response of Y between A and D group for a given value of X_1

Estimate $\beta_3 - \beta_4$

- 1. $b_3 b_4$
- 2. $Var(b_3 b_4) = var(b_3) + var(b_4) 2cov(b_3, b_4)$

If doing time series, one can use indicator variables to model time periods

8.2 Model and Variable Selection

8.2.1 Criterion for Model Selection

p: # of parameters (regression coefficients)

1. \mathbb{R}^2_p or SSE_p criterion. Both indicate the same thing.

$$R_p^2 = 1 - \frac{SSE_p}{SSTo}$$

Look for

- High R_p^2
- $Small\ SSE_p$
- 2. $R_{a,p}^2$ or MSE_p criterion

$$R_p^2 = 1 - \frac{\frac{SSE_p}{n-p}}{\frac{SST_o}{n-1}} = 1 - \frac{MSE_p}{\frac{SST_o}{n-1}}$$

Look For:

- High $R_{a,p}^2$
- $Small\ MSE_p$
- 3. Mallows' C_p Criterion

$$C_p = \frac{SSE_p}{MSE(X_1, \dots, X_{p-1})} - (n-2p)$$

 $MSE(X_1,...,X_{p-1})$: MSE for the model with **all** potential predictors of interest

For largest possible value of P, $C_p = p$

proof

$$MSE = \frac{SSE}{n-p}$$

$$\frac{SSE_p}{\frac{SSE_p}{n-p}} = n - p - (n-2p) = p$$
(35)

Look for

• Small C_p or $C_P \leq p$. This means the model has a small amount of bias

Recall
$$MSE(Y) = Bias^2(Y) + Var(Y)$$

- 1. AIC_p or SBC_p Criterion
 - AIC_p : Akaike's Information Criterion $nln(SSE_p) nln(n) + 2p$
 - SBC_p : Schwartz' Bayesian Information Criterion $nln(SSE_p)$ nln(n) + pln(n)

Look for

- $Small\ SSE_p$
- $Small\ AIC_p\ and/or\ SBC_p$
- 2. $PRESS_p$ Criterion

Prediction Sum of Squares

$$PRESS_P = \sum_{1}^{n} (Y_i - \hat{Y}_{i(i)})^2$$

 $\hat{Y}_{i(i)}$

- (a) Ignore the ith case
- (b) Fit model on remaining n-1 cases
- (c) Find Fitted value based on deleted ith case

This is **not** the same as bootstrapping, mostly because there is no resampling oging on.

```
leaps::regsubsets(formula, data, method="exhaustive", nbest=30)
#+NAME: fortify_leaps
fortify.regsubsets <- function(model, data, ...){
   require(plyr)
   stopifnot(model$intercept)
   models <- summary(model)$which
   rownames(models) <- NULL
   model_stats <- as.data.frame(summary(model)[c("bic","cp","rss","rsq","adjr2"]
   dfs <- lapply(coef(model, 1:nrow(models)), function(x) as.data.frame(t(x)))
   model_coefs <- plyr::rbind.fill(dfs)
   model_coefs[is.na(model_coefs)] <- 0</pre>
```

```
model_stats <- cbind(model_stats, model_coefs)
# terms_short <- abbreviate(colnames(models))
terms_short <- colnames(models)
model_stats$model_words <- aaply(models, 1, function(row) paste(terms_short[:
model_stats$size <- rowSums(summary(model)$which)
model_stats
}

get_model_coefs <- function(model){
   models <- summary(model)$which
   dfs <- lapply(coef(model, 1:nrow(models)), function(x) as.data.frame(t(x)))
   model_coefs <- plyr::rbind.fill(dfs)
   model_coefs[is.na(model_coefs)] <- 0
   model_coefs
}</pre>
```

9 Session 9 - Model and Variable Selection & Assessing Diagnostics

9.1 Model and Variable Selection

9.1.1 Automatic Search Procedures

1. Backward Selection

```
Full Model -> reduce parameters to "smallest" AIC
step(model.full, direction = "backward")
```

2. Forward Selection

```
Intercept-only model -> add parameters to "smallest" AIC
step(lm.null, scope = list(lower, upper), direction = "forward")
```

3. Step-wise

```
Intercept-only model -> add one -> subtract\/add one for "smallest" AIC
```

```
step(lm.null, scope = list(upper), direction = "both")
```

9.1.2 Model Validation

1. Collect new data t ocheck the model and it's predictive validity

$$MSPR = \frac{\sum_{1}^{n^*} (Y_i - \hat{Y}_i)^2}{n^*}$$

If MSPR approximately your Model's MSE, then your model is not necessarily biased. If the difference is large, MSPR is a good indicator on how well it predicts.

Defintions

- MSPR: Mean Square Prediction Error
- Y_i : Value of the response variable in the ith validation case
- \hat{Y}_i : Predicted value of the ith validation case using the model you previously built.
- n^* : number of cases in the validation dataset.
- 2. Compare results with theoretical expectations empirical results, and simulation results.
- 3. Use a holdout sample to check the model and its predictive ability. This is standard practice for predictive models

9.2 Assessing Diagnostics

9.2.1 Added-variable Plots

Also known as:

- Partial Regression Plots
- Adjusted Variable Plots

These plots show:

- Marginal Importance of this variable in reducing residual variability
- May provide info about the nature of the marginal regression relation for predictor variable X_k under consideration
- 1. Example $Y_i = \beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \epsilon_i$

Goal: What is X_i 's effect given that X_2 is in the model?

$$\hat{Y}_i(X_2) = b_0 + b_2 X_{i2}
e_i(Y|X_2) = Y_i - \hat{Y}_i(X_2)$$
(36)

 $fitted\ values\ +\ residuals\ from\ the\ model\ with\ only\ X_2$

$$\hat{X}_{i1}(X_2) = b_0^* + b_2^* X_{i2}$$

$$e_i(X_1|X_2) = X_{i1} - \hat{X}_{i1}(X_2)$$
(37)

fitted value + residuals from the model with X_1 as the response and X_2 as the predictor.

2. Reading Plots

car::avPlots(model)

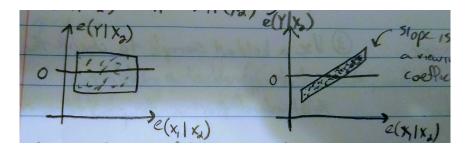

Figure 7: Partial Residuals vs Fitted Values

- (a) Partial Residuals X_1 vs Fitted Values Notice the even distribution of residuals around y = 0. X_1 provides no useful information given X_2 is in the model.
- (b) Partial Residuals X_2 vs Fitted Values Notice the pattern. X_1 may be a good addition to the model given X_2 is already in the model.

Goal: Identify outlying Y observations. i.e. which Y observations are influential on our own regression model?

• Residuals: $e_i = Y_i - \hat{Y}_i$

• Semi-studentized Residuals: $e^* = \frac{e_i}{\sqrt{MSE}}$

• Studentized Residuals: $R_i = \frac{e_i}{\sqrt{MSE(1-h_{ii})}}$

 h_{ii} : the ith diagonal value from the hat matrix H

rstandard(model)

10 Session 10 - Outliers & Weighted Least Squares

10.1 Outliers

10.1.1 Identifying Outlying Y Observations

• Use Studentized Deleted Residuals to identify outlying Y Observations

Residuals: $e_i = Y_i - \hat{Y}_i$ Semi-studentized Residuals: $e_i^* = \frac{e_i}{\sqrt{MSE}}$ Studentized Residuals: $r_i = \frac{e_i}{\sqrt{MSE(1-h_{ii})}}$

 h_{ii} : Standard Error of e_i . aka Standard Error of the ith residual

Deleted Residuals: $d_i = Y_i - \hat{Y_{i(i)}} = \frac{e_i}{1 - h_{ii}}$ Studentized Deleted Residuals (rstudent):

$$t_{i} = \frac{d_{i}}{SE_{d_{i}}}$$

$$= \frac{e_{i}}{\sqrt{MSE_{(i)}(1 - h_{ii})}}$$

$$= e_{i}\sqrt{\frac{n - p - 1}{SSE(1 - h_{ii}) - e_{i}^{2}}}$$
(38)

10.1.2 What is an Outling Y Observation?

$$|t_i|>t_{1-rac{lpha}{2n},n-p-1}$$
 qt(1 - alpha / 2n, n - p - 1)

• The "-1" is the residual that is being deleted

10.1.3 Identifying Outlying X Observations

• Use leverage values. i.e. "hat matrix leverage values"

 h_{ii} : leverage (in terms of X values)

- 1. $0 \le h_{ii} \le 1, i = [1, n]$
- 2. $\sum_{i=1}^{n} h_{ii} = p$ (number of parameters in the model)

Recall: $Var(e_i) = MSE(1 - h_{ii})$

• The larger h_{ii} , $Var(e_i)$ decreases, thus making close to Y_i \$

How large is a large h_{ii} ?

• if $h_{ii} > s\bar{h} = \frac{2p}{n}$, the cases are outlying cases in terms of X.

10.2 Influential Cases

How influential are "new" cases?

$$h_{new,new} = X_{new,new}^T (X^T X)^{-1} X_{new,new}$$

If $h_{new,new}$ is much larger than h_{ii} , there may be some extrapolation. There are no set guidelines for this.

10.2.1 Identifying Influential Cases

- 1. Influence of the ith case on a single fitted value, .
 - Use DFFITS (Difference of Fits)

$$DFFITS_{i} = \frac{\hat{Y}_{i} - Y_{i(i)}}{\sqrt{MSE_{(i)}h_{ii}}}$$

$$= e_{i}\sqrt{\frac{n - p - 1}{SSE(1 - h_{ii}) - e_{i}^{2}}}\sqrt{\frac{h_{ii}}{1 - h_{ii}}}$$

$$= t_{i}\sqrt{\frac{h_{ii}}{1 - h_{ii}}}$$
(39)

Notes

• $MSE_{(i)}$: calculated with the ith case removed

• t_i : Studentized Deleted Residuals

What is influential?

- Small Med Dataset: $|DFFFITS_i| > 1$
- Large Dataset: $|DFFITS_i| > 2\sqrt{\frac{p}{n}}$
- 2. Influence of the ith case on all fitted values
 - Cooks Distance

$$D_{i} = \frac{\sum_{j=1}^{n} (\hat{Y}_{j} - \hat{Y}_{j(i)})^{2}}{pMSE}$$

$$= \frac{e_{i}^{2}}{pMSE} \left[\frac{h_{ii}}{(1 - h_{ii})^{2}} \right]$$
(40)

Notes

• $Y_{j(i)}$: fitted value when the ith case is left out

What is an influential case? Compare D_i to $F_{p,n-p}$

- If $P(F_{p,n-p} \leq D_i) < 0.1, 0.2$, the ith case has very little influence.
- If $P(F_{p,n-p} \leq D_i) > 0.5$, the ith case has major influence.
- 3. Influence of the ith case on the regression coefficients
 - DFBETAS $(DFBETAS)_{k(i)} = \frac{b_k b_{k(i)}}{\sqrt{MSE_{(i)}C_{kk}}} \text{ Notes:}$ $C_{kk} : \text{ Diagonal term of } (X^TX)^{-1}$ $Var(\vec{b} = \sigma^2(X^TX)^{-1} = \sigma^2C_{kk}$

10.3 Variance Inflation Factors

• used to assess Multicollinearity

$$VIF = \frac{1}{1 - R_k^2}$$

Notes

$$-R_k^2$$
 is R^2 from 'lm(Xk ~ X1 + \dots + X(k-1) + X(k + 1) + \dots + X(p - 1))'

* This is a mishmash of math and R

$$\min \, \mathrm{VIF}_k = 1 \, \max \, \mathrm{VIF} = \infty$$

- Sometimes (rarely) signs flip
- multicollinearity causes increase variance

Interpretation

- VIF > 4, mild/moderate multicollinearity
- VIF > 10, severe multicollinearity
- Ideal? $V\bar{I}F$ close to 1

If experiencing high multicollinearity, check for correlation between response and each predictor.

10.4 Weighted Least Squares

• Good use if Variance is Unequal

Possible Weight: $W_i = \frac{1}{\sigma_i^2}$

10.4.1 Iteratively Reweighted Least Squares

- 1. Fit regular least squares model and analyze results
- 2. Estimate the variance function or the standard deviation function by regressing e_i^2 or $|e_i|$ on the predictors.
- 3. Use the fitted values from the estimated $Var(\hat{V}_i)$ or estimate std. dev (\hat{S}_i) function to obtain weights w_i .
- 4. Estimate regression coefficients use the weights. So?
 - e_i^2 estimates σ_i^2
 - $|e_i|$ estimates σ_i

$$W_i = \frac{1}{(\hat{S}_i)^2} \text{ using } |e_i|$$

$$\mathbf{OR}$$

$$W_i = \frac{1}{\hat{V}_i}$$
 using e_i^2
